2021-pgcma-38@nca.edu.pk

Abstract

AI is the most disruptive technology of the decade as it changes industries for the better by upgrading processes, increasing efficiencies, and introducing creativity in many industries. The liberties, in this case, are seen in health care where artificial intelligences is changing the ways diagnosis's are done, treatment methods, drug discovery and many more. Some of the potential applications of AI in the petroleum industry include; Efficiency in the production of energy, issues to do with safety and even with those of maintenance with emphasis on prevention of future mishaps that may be costly or fatal. AI has also found its use in anti-fraud where it is applied to identify new financial crimes and encode machine learning models to adapt to their new schemes. Categorized under cyber security, Artificial Intelligence is strengthening the cybersecurity by identifying new threats, making accurate forecasts, and responding to threats proactively to protect sensitive data. A well-known example of conversational AI is the Chatgpt is one of the key applications of the AI industry. Chatgpt is disintermediating customer service, sales and internal communication by providing a highly personalized many turn contextually aware conversation. Making communications with customers faster, and more efficient and thus is a win-win for customers as well as the organization. It also enhances the issue of accessibility since it facilitates communication between different user groups. At the same time, when AI became more successful and extensively integrated into multiple company processes, it created new specific ethical concerns, such as data privacy, bias, and insufficient transparency. It is crucial to solve these problems to get the highest advantage from AI and do not cause distrust and misunderstanding. This current role of AI is set to grow in the future, across sectors, to deliver even higher levels of effectiveness, creativity and convenience, unlocking the era of a smarter connected world.

Key words

Healthcare, oil and gas, fraud, cybersecurity, Chatgpt, conversational AI for healthcare, AI ethical issues, availability, productivity enhancement, predictive analytics, ease-of-use.

Introduction

Artificial Intelligence is penetrating deeply into the caring industry and has quickly changed the approaches to achieving healthcare goals in such spheres as patient management, diagnostics and treatment, research. There can be no doubt that as technology advances ever further, AI can also

play a pivotal role in making the services of treating patients qualitatively better and more efficient, with demonstrable potential to advance the achievements of medical practices and reduce expenses. AI's most utilized aspect without doubt is diagnostic where its influence has been most profound in health care [1]. The conventional processes of diagnosing the foetal positioning and presentation are sometimes tiresome, costly and occasionally influenced by human dexterity. In today's world, AI-based medical image analysis has become possible on a previously unseen level. ML systems are useful for identifying various diseases including cancer, heart problems, neurological disorders with the help of the medical scans (X-rays, MRI, CT scan etc). For instance, Google's Deep Mind has shown proficiency in identifying diseases such as eye diseases, as well as breast cancer through reviewing thousands of images, in most cases with higher accuracy than that of doctors. The effect is especially pronounced in areas where specialists are scarce; in such a case, AI brings value as an assistant to healthcare practitioners in identifying potentially difficult cases [2].

AI is also used in another important area known as personalized medicine. Based on program applied to large number of patients, genetics, past medical history, current treatments, life statistics and the likes, artificial intelligence system is capable of suggesting the most appropriate treatment for a patient. Such a level of tumor specificity could eventually change the approach toward the treatment of various diseases such as cancer, characterized by low efficacy of the standard treatment for most patients [3]. AI can discover the patients' genotype and prognosis to treatment in order to avoid the guess and check method of drug administration, thereby increasing the rates of success of the treatments given. In the concept of drug discovery, AI is helping to Hans soon some of the new drug and terrific concepts. Joined with other essential costs of drug development separately and from other studies, the process conventionally lasts for years and requires billions of dollars and has a high risk of failure. For instance, in cases of existing chemical compounds, clinical trials or molecular research data, AI can predict which of the chemical compounds should be effective in tackling certain diseases. The same goes for predicting how drugs effect human body and genomics, allowing researcher to find better candidates faster. This has been evident in the recent platforms on developing vaccines for instance, COVID-19 where AI had the responsibility of accomplishing rapid vaccine predictions and analysis of stability [4].

Another bright spot in the use of AI is in the field of prediction analysis. Detecting patient outcomes from enormous amounts of healthcare data through the use of AI algorithms can assist in early preventive measures and management accordingly to which resource is best allocated where. For example, using the patient's records, AI can predict signs of a predisposition to chronic diseases such as diabetes or heart diseases when they are still not detectable. This leads to early interventions taking action such as a change in lifestyle or a treatment which not only leads to many positive long-term health aspects but also decreases overall expenditure of health [5]. AI is also making the managerial aspect of healthcare easier by handling some normal tasks like appointment, invoice, and paperwork. It relieves pressure off healthcare workers to work for long hours, performing clerical duties and provides the much needed freeing up of time for health care providers to diagnose and treat illnesses. For instance, through artificial intelligence, organizations can use chatbots and virtual assistants to attend to patients' inquiries, the booking of appointments as well as responding to simple queries related to symptoms and health problems among others, all these would go a long way in enhancing the overall patient relations and reduced waiting time [6].

Besides, AI has the capability to reduce the inequality in healthcare center access especially to the underdeveloped and rural regions. With artificial intelligence in shaping telemedicine, it became easier for patients to gain consultations and medical advice while avoiding physical travel. AI can also be deployed to keep track of patients' health using wearable technology in order to observe non-stop any changes in his/her health status. The current 'remote monitoring' is particularly beneficial where patients are known to have chronic diseases eg hypertension or diabetes where any development of complications require early intervention. AI is becoming a boon for medical research because it helps researchers to cope with formidable challenges associated with analyzing scientific literature, clinical trial outcome, and huge patient data. AI may find out new patterns out of previously unseen data the presence or methods which can quickly improve the existing knowledge of diseases, the approaches to their treatment, or the healthcare system as a wholeness. Also, the use of artificial intelligence is growing to select and organize the clinical trials more

effectively, meaning that the most effective treatments are being delivered to patients as soon as possible [7].

This is not only improving the efficiency of present therapeutic approaches, diagnostics, and research but opening up new opportunities for medicine utilizing an artificial intelligence tool. Using AI for medical diagnosis, unparalleled treatment methods recommendation, rapid development of drugs, and accessibility of healthcare at improved efficacy, this technology has the ability to revolutionize the healthcare sector [8]. Sustaining the development of these technologies will result in even greater innovation and enhancement of quality in patients' care, costs reduction, and overall creation of effective healthcare system in the future internationally.

AI Advancements in the Petroleum Industry: Improving the efficiency and innovation level

Historically the petroleum industry has been an important mature driving force for the global economy providing energy resources and supporting industrial development. But it also found itself to be struggling with certain issues including the soaring and falling prices of oil, and pressure on environment, and need for operational excellence. This paper focuses on the impact of Artificial Intelligence (AI) within the petroleum industry in the recent past to the future as the industry continues to evolve. Through the application of AI, the petroleum firms have improved the development, production, refining and even supply chain of their products all in an attempt to improve the efficiency of their operations in the business world. The most significant effect of AI in the petroleum industry is in exploration & Reservoir Management. Legacy approach to oil exploration has involved the use of data, maps and other geological surveys as well as drilling and blowing to determine the possible reserves [9]. While these methods are helpful, they may take lots of time, energy and money, and sometimes yields erroneous results. Using the ML & DL algorithms, AI has enhanced the ways of performing exploration by providing better results in lesser time.

Calculating from these data sets is manageable by AI tools, data such as seismic surveys, satellite images, historical drilling data, and more to map out the likely locations of unexploited oil deposits. With the help of AI in real time processing, this data can accurately build more geologic models

to save time and money to discover new oil fields. In addition, it can be applied in genetic algorithms and curve fitting to predict reservoir behavior of the oil and gas, which can make companies better inefficient in their resource take. This cuts cost, increases recovery rates and increases the life cycle of the oil fields [10]. Another area that has shown a tremendous application of AI is on the aspect of the petroleum industry's use of Predictive Maintenance. Maintenance becomes an issue of significant concern because the exploration, extraction and refining procedures entail the use of several and sensitive machineries and infrastructure. Equipment failures occur when they are not anticipated and this may cause downtime, opening up of safety hazards and operation costs. Such risks are addressed by prescriptive analytics of data generated from such sensors in equipment through use of AI speeds up this field of maintenance [11].

From other field data, there is an ability to use analytical data from the sensors so that machine failure can be predicted and maintained earlier not to happen. This not only assists us with getting less unexpected downtime but also increases the useful life of devices and decreases repair expenditures. For instance, AI can learn signals from the drilling equipment vibration or pressure from the pipeline and diagnose any signs of wear. If these problems are handled adequately, cleaning companies in the petroleum industries will be able to cut their expenditure on maintenance as well as enhance safety measures [12]. It is also useful in the petroleum industry where most circumstances involve some form of risk that AI is helping to enhance safety and risk control. Exploitation and transfer of oil and gas may take place in regions of hostile terrains or climates including offshore drilling platform, deep water exploration or lengthy pipelines. Such operations are currently being supervised using real-time AI-powered systems, making it possible to detect preconditions of undesired states and subsequent accidents or catastrophes during the execution of operations [13].

For instance, AI can consider data from sensors fitted in offshore platforms, a signifying great pressure, temperature or a break in gas which may lead to a disaster. Also, AI-based systems can train operators by creating almost-real emergency situations for the best safety working algorithms. These are new and valuable in the sense that they are enabling organizations to lower the risk of

incidents, provide a faster and more effective intervention, as well as prevent harm to employees and adverse impacts on the natural world. In refining and production optimization AI has been widely implemented in the modern world [14]. Refinery is integrated process units that involve conversion of crude oil to a range of products including gasoline, diesel and petrochemicals. The other important problem of refineries is to achieve the maximum result of yield and at the same time, the minimum of costs and energy consumption in the course of production. Having operation data available in real time, such as temperature, pressure, flow rates and others can be analyzed by AI algorithms to improve refinery's operations. For instance, system can predict the best input values to be used in the distillation process of a refinery so as to get the maximum yields of valuable products from the feeds. Also, through the use of AI, it is possible to maintain real-time control of operations and adapt parameters corresponding to feedstock changes, which makes refining more effective and economical. This leads to increased production, lower energy consumption and the emissions output [15].

AI is also being used in the modern world to improve the supply chain in the specific region of the petroleum sector. As products, the handling and delivery of oil and gas products are very technical requiring pipelines, ships, and refineries that cover vast regions of a country. These supply chains are currently adding AI to make their logistics more efficient by using improvements in demand forecasts, weather conditions, and routes to find the best way to deliver their stocks without delay. For instance, AI can determine supply and demand changes and organize a company's supply chain correspondingly to optimize expenditure [16]. Also, AI can suggest effectively navigate through the roads so that the consumption of the fuel, weather conditions, and the possibility of the infrastructure are considered. In this way, through general organizational improvement and optimization of these operational odd jobs, AI contributes to improved operational efficiency, lower costs, and better delivery times, so that a product will finally reach the consumer. AI is assisting the petroleum industry adopt sustainability and reduce the rising environmental issues. With the global push towards clean energy, the petroleum industry is gradually under pressure to reduce its emission levels. To be specific, AI can be used in the optimization of energy bills specifically in the extraction and refining processes, in cutting down losses and in the monitoring

of emissions. AI models can predict carbon emissions rates and determine where emissions can be optimized, all while also overseeing compliance with environmental laws [17].

This paper aims to review the applicability of AI technologies, types, and impacts on the petroleum industry to improve the efficiency, safety, and sustainability of its methods. The traditional workflows of exploration and extraction, refining and all supply chain functions are benefiting from AI and becoming more innovative and cheap. In future, these problems, including unpredicted prices, environmental issue, and new technologies will remain significant in the petroleum industry and AI will take its role to help petroleum companies to compete and sustain themselves as well as ensure the environment in the ever challenging global energy market [18].

AI-Powered Fraud Detection: building-up financial stability and insuring against future risks

Scams and swindles, such as financial swindles, Internet scams or phishing, and identity theft, remain a grave threat to companies, people, and world economies. For these elaborate fraud businesses, the conventional paperwork screening or simple set-apart rules that involve decision-making trees are professionally insufficient. To this end, AI has been a new solution that has been very crucial everywhere in the prevention of fraud since it surpasses any other tool to detect, prevent, and mitigate fraud [19]. Machine learning, deep learning with big data analytics are progressing the main field of AI in the areas of banking, insurance, e-commerce, and government fraud detecting. The first advantage which AI has in regards to fraud detection is the capability of learning through large volumes of data and being able to pick out specific patterns which would not be easily noticeable. In traditional fraud detection systems, analysts initially look for fraud by analyzing transactions or behavior and this is tedious, prone to errors, and cannot cope with the increasing volume of data. AI systems, on the other hand, can perform millions of transactions at once, check them against past histories and the suspected fraud indicators to produce greater accuracy in detection of fraud [20].

Benefits of Fraud detection

Figure: 1 showing benefits of fraud detection in lending

Fraud detection is an ideal application of machine learning algorithms which belongs to the AI category because it can be trained on a large set of data with both genuine and fake transactions. These algorithms build up the capability to detect and distinguish intricate patterns between transactional data, customers' behavior and other external conditions suggestive of fraud. For instance, the AI model could be designed to identify a customer's spending frequency and pattern and raise an alert, where activity, which is inconsistent with the standards, is noticed say a large purchase or a transaction made in another geographical location [21]. The larger the sample size

of data in the AI system the higher the likelihood of accurate real-time detection of fraudulent activities. The real strength of using AI in the fraud detection is the capacity to evolve as the fraudsters alter their approach. While fraudsters never cease to find ways to avoid the notification of usual detection procedures, AI solutions are capable of changing detecting procedures by learning more about the new patterns of fraud. For example, fraudsters may use strategies more advanced than traditional fraud; synthetic identities, account takeover, or money laundering, etc., that hard for rule-based models to pinpoint. However, AI approaches can be built to learn and update the models that they use to detect the existence of new fraud schemes and reduce false alarms [22].

In banking and financial verticals, AI is helping in identifying a spectrum of financial crimes such as credit card frauds, corporate frauds, insider trading as well as money laundering. The old generation credit card fraud detection engines, therefore, usually use set initial rules or censors like any transaction above or equal a certain dollar figure or purchase made from a place not previously known to the card holder [23]. Despite this, such systems have their fair share of effectiveness, though they produce lots of false alarms that are not perfect for customer sales and satisfaction. AI driven systems are more flexible and therefore they take into consideration things like how a user normally transacts, the time, type of merchant among other factors. This makes it easier for AI to identify fraud and at the same time minimize on false positives. AI is also very helpful in determining anti-money laundering (AML) where the financial institutions such as banks have to identify and avoid processing of such funds. Mainstream AML systems employed practical methods based on the application of checklists and a human operator's decision-making in identifying suspicious transactions. AI, however, can concurrently audit different layers of extensive networks of transactions in real time and compare extraordinary patterns of different accounts and institutions. Using machine learning, AI is capable of spotting money laundering schemes of a higher level, including layering and structuring which cannot be identified with the help of conventional methods [24].

In the insurance domain it is being utilized to detect fraud in the process of claims. Scam and fake report—which include exaggerated or faked reports—contribute to the insurance industry losses worth billions of US dollars every year. Claims processing involves using appropriate algorithms in the examination of claim data and records that show red flags relating to fraudulent activities. For instance, an AI system could make decision as to whether the timing of a specific claim fits within a range of similar claims, verify repair cost, or determine whether other related claims in a customer's previous history were fraudulent. In addition, it is possible to include in AI systems the data sources from other sources like social networks, public databases, etc., to filter out which of the claims are potentially fraudulent [25]. AI has also started making its ways into the e-commerce platforms for handling fake transactions occurring in the online business. As people are now using Virtual Stores, credit card fraud is one of the significant issues nowadays. Traditional methods of detecting fraud include chargebacks on credit card, account takeover, fake review and among others which AI can identify in real time. Machine learning algorithms that read these values can see how hastily the users are purchasing products, from which IP addresses they are logging into the same accounts, or with some different shipping addresses. This allows e-commerce companies to avoid fraud occurrence and also help to safeguard the general public, and merchants.

It is worthy of note that AI in fraud detection averts one major drawback most traditional systems have that involve high rates of false positive, that is, the act of tagging genuine transactions as fraudulent ones. Thus in industries where the customer experience is key such as banking the wrong predictions frustrate the customers and they loss trust [26]. The application of AI systems enhances accuracy, bearing in mind that it takes into consideration a large number of factors and modifies its detection programs as it evolves. Reduction of the false positives is important in improving the overall customer experience and the cost of manual investigation. Also, AI can improve the effectiveness of processes for fraud detection.

First and foremost, automated AI systems can work day and night providing constant analysis of transactions, behaviour and other data that may come in handy. This eliminates the time spent monitoring and enhances the speed for identification of the anomalies, which is important in

curtailing fraud before they aggravate. It is possible for AI-powered systems to learn patterns of threats depending on the level of threat; the analysts will then only concentrate on high threat cases while AI handles the low threat cases. With fraud continually becoming sharper in form, AI proves to be a more vital weapon for businesses or organizations to deter fraudsters [27]. With an active AI AI AI AI AI use, it becomes easier for any organization to protect against fraud, win back the confidence of its customers, and meet the different regulatory obligations put in place. As AI has the potential of learning from large amounts of data, aware of new fraud practices, and enhance accuracy In the long run, the technology is quickly changing how fraud is identified and prevented making the future financial environment more defended.

Cybersecurity in the Age of AI: The risks and threats affecting businesses and its customers and tenants are also isolated and discussed below.

Ever with the advent of the world economy going online, cybersecurity has become one of the most important issues facing the modern society. A current threat landscape is marked by an ever-rising frequency and severity of cyber threats that utilize ever more complex tactics to breach programs and networks, siphon information, and damage companies' financial and brand images. To protect again these threats, the traditional technological measures of cybersecurity, which are mainly based on the virus signature detection and analysts' intervention, became inadequate. AI is consequently central in shaping the future of cybersecurity by enabling proactive identification, anticipation, and counteraction of sophisticated cyber threats in real time and in real space. ML and deep learning algorithms help integrate AI-based solutions improve threat detection, automate responses, and adapt the defense systems of an organization [28]. One more benefit that AI possesses in the sphere of cybersecurity is the capacity to identify a certain number of patterns and activity types that a human operator cannot recognize. Intrusion detection systems are suggestively based on rules prescribed by Organizations for Information security)Then, therefore their ability to detect new, unknown, or developing threats is severely constrained. AI, however, can always be running in networks and systems and learn from other data and identify anomalies from the

norm. This makes AI especially good at identifying zero-day threats – brand new types of threats that are yet to be included among the databases of a traditional security software [29].

In AI-based systems of cyber defense, machine learning algorithms are trained on a variety of data which contains both typical behavior of the system and attack scenarios. Then, using this training, these models search for the anomalies in real-time: for instance, unexpected logins, data transfers or unauthorized access to the valuable data. For example, AI can analyze incoming traffic with activity logs and detect potentially fraudulent traffic, which is typical for a Distributed Denial of Service (DDoS) attack since initially it looks like regular traffic. Altogether, AI provides an opportunity to identify threats that may cause great losses or damages and then avoid them. The third pro of employing AI is that it can independently power threat vigilance and defense. Many legacy cybersecurity solutions rely on people to analyses threats and respond to them, which results in time lags and failure to seize opportunities for threat neutralization. While AI can also work with a tremendously large amount of data in real-time, in addition to recognizing possible threats, it can also act on them without input from a human [30]. For example, if an AI system recognizes an attempt to breach data or gain unauthorized access, in the system, it can immediately follow the preprogrammed set of actions that, for example, may involve disconnecting the affected system, blocking IP addresses of intruders or calling upon AI security teams to investigate. This a fast response aid in preventing the menace from progressing and causing worst impacts.

Automated systems also are being enhanced in the identification of Phishing, which is one of the most common cyber threats. Spear phishing where a would be attacker pretends to come from a reliable source and gets the victim to surrender private information is on the rise. To counter attacks from phishing, AI is employed in pattern recognition in language structure in emails/ sending patterns in Web links [31]. For instance, NLP methods of AI can be applied to the body content of an email and notify the receiver if the language used is suspicious, similar to normal phishing lingo, or different from the normal communication pattern of the senders address. Another way of using AI is to compare URLs with known dangerous sites and, thus, provide more protection from phishing attacks. Another area that AI is making a very strong impression is in the security of

endpoints. In today's culture, many forms of devices such as; laptops, smartphones, tablets, and IoT devices are in use for connecting to an organization's network and data. This is the first endpoint that through their vulnerability, cybercriminals could easily launch an attack on an organization. Endpoint protection and response (EDR) software are AI embedded and work in a way that they constantly analyze the activities in end-user devices and network connections to identify any anomalous behavior. For instance, if a device starts pumping large amount of data to an external server or running processes that are nonexistent should trigger the AI system as suspicious. Through an ability to identify such anomalies AI can help prevent further exploitation in the form of a security breach [32].

AI also has a significant function in recognizing and decreasing cyber threats before they happened. By reviewing figures obtained from attacks, weaknesses and other forms of malicious actions, AI is capable of finding out future attacks. With such a predictive power at their disposal, organizations can effectively anticipate and reinforce their protection against certain kinds of cyber threats. For instance, AI can be used to predict incoming attacks on a network because the emergence of relatively new threat actors or spikes in specific types of cyber threats have been identified. Such threats can then be anticipated allowing organizations to proactively modify security, apply relevant patch and deploy more security measures. In addition, AI is improving Security Information and Event Management (SIEM) systems in the operations that need to be managed [33]. SIEM stands for Security Information and Event Management is a software that gathers data on security events from various areas of an organization's network; nonetheless, the amount of this data is often unrealistic for analysts to analyze. Log data is then preprocessed and analyzed using AI algorithms that can filter through massive data for target patterns and potential anomalies for manual analysis. Since this process can be fully automated, the AI based SIEM systems can provide filters to give the most prioritized security events to the tuned in security personnel decreasing the efforts given to less threatening security situations [34].

Aside from threat identification and even combating them, AI is also playing a role where there has been an attack and where recovery is being sought. In healthcare, AI can help in post-cyber-

attack triaging by determining where the cyber-attack accessed the system, how the cyber-attack happened as well as enabling the medical security team to grasp the attack's ramifications. AI systems can take logs, traffic in a network and any related information to model the sequence of events in an attack and establish which weaknesses were exploited. This data will be crucial and significant to avoid future attacks and enhance the security compliance of the organization. With organizations shift into cloud environment and different digital initiatives, AI is now recognized as an important aspect within cloud security [35]. AI can provide safety to cloud infrastructures by detecting, who is accessing the cloud storage system or what are the weaknesses in that system, who is trying to get unauthorized access to it and what patterns of transfer of data are different from the normal. AI furthermore helps to guarantee that data is shielded from new threats if this data is distributed across the multiple servers and multiple locations, including CSPs.

Chatgpt and the Future of Conversational AI: Cui EAC: Customer Interaction, Interaction and Relationship Management

In this Information age and the digital age, the implementation of conversational AI grounded in natural language processing and machine learning is the powerful tool today's business and organizational world. The numerous progressive technologies that go with day to day business life including virtual personal assistants, live chat robots and automated customer care solutions add an extra facet of speedy customer relations. A current state of the art AI conversational model is Chatgpt, which is a current state of the art language model developed by OpenAI. ChatGPT is an extremely novel conversational AI system developed from Generative Retrained Transformer architecture for people and machine interaction that constitutes nearly natural discourse. The pro of Chatgpt includes them moving to the next level of conversational interfaces and; It is also way more advanced than basic interfaces because it includes conversation, turn taking and contextual understanding. It can even work with words which make a concrete response like human beings do, this makes it easier to apply the given product in many sectors [36]. While customer support, sale and marketing have integrated Artificial Intelligence for different operations, Chatgpt has been very helpful in improving the quality of such services.

Chatgpt is just one of the conversational AI applications, and customer support is widely known to be its core use case. This is especially true owing to its serious drawbacks such as long response time, high cost and indeed, poor quality of service common with conventional customer care such as calls and emails. As result of the levelling up of this branch an interface help to improve the customer service is fast, effective and can be offered anytime. Chatgpt enhances this in a far more conversational, contextual, and personalized manner. By answering simple questions, taking orders, payments or even solving complaints and concerns, Chatgpt has an ability to do it autonomously without any human involvement. For example, availability of stock, time of delivery or, returns policy issues are some of the things a client with can ask an AI an chatbot from Chatgpt. Employers can respond immediately, provide relevant and specific information of the customer which is useful to the whole process. This eliminates the case where human agents spend much of their time performing tasks which would be more efficiently handled by an artificial system, and give them time to handle queries that the artificial system cannot tackle [37].

Also, which provided Chatgpt features to become a multi turn conversations it can reply to the user with the previous message as a context. It is most helpful where the customer finds it hard to comprehend and the different instructions, for example in the process of solving a technical question. By using context implementation, Chatgpt ensures that it is responding in line with the previous responses making the situation a lot less cumbersome to customers who would have to describe their issues severally [38]. This is not only valid in customer's support, but Chatgpt is quite useful also in sales and marketing area. By integrating conversational models like Chatgpt, it is possible to retarget potential clients on sites like e-commerce and on social media, asking those questions about the products, they may like or suggesting products related to their choices. It can therefore be utilized in the enhancement of sale through customer relations, advice giving, encouragement to purchase more and offering related products.

For example, Chatgpt, in the environment of an online retail store, can capture browsing history of a customer, his purchase history and preference to forward relevant products to him thereby raising the chance of conversion rate and sales volume. Also, the AI can answer customers as soon

as possible with their questions and reduce the bureaucratic load that negatively affects buyers, as a result, increasing buyers' confidence in the decision-making process. Chatgpt also assists in the more or less automation of leads since one is able to talk to a prospect while they conduct some of their searches or even fetch their details, call back or schedule another appointment for the Sales person. Especially in the marketing field, Chatgpt can help massively extend the tactic of creating and producing highly individualized media [39]. This can assist the business organization to create content for emails, social media and advertisements from the interest of the customer and his interaction with the web page. Hence, with the aid of language processing and generation, Chatgpt assist several companies to engage or market directly to customers automatically. The same personalization makes the chance of the customer interaction high while at the same time enhancing the brand value.

But I have grasped How Chatgpt can be used in Organizations as apart from client facing applications it can also be used internally to improve communication and cooperation. The various teams end up being overwhelmed by the stream of information and especially on how to go around the various tasks that are accorded to them as organizations grow especially the business oriented operations of such firms. ,On the internal communication level therefore Chatgpt can be of help in the capacity of a corporate assistant in a way that it provides information where necessary, and as a reminder on dates and schedules and works scheduling among employees [40]. For instance, it can integrate with team collaboration, and message apps like slack, Microsoft teams, or even work with Asana to guide employees on answers to the questions. Some workers may want to ask some questions concerning some policies followed in the company or even some due dates, or even some nuances of an ongoing project and all these questions and answers can be provided instantly by Chatgpt. This is useful for employees, especially in order not to spend time looking using search by email or documents. However, it is also present an opportunity to generate understanding of agendas, accepting or declining meeting invitations and even writing e-mails or preparing reports by using AI systems like Chatgpt [41].

It is also a fantastic opportunity that conversational AI like Chatgpt can potentially increase access and diversity. By addressing capability of Chatgpt in handling natural language to a real time level the disabled Bod is in a position to appreciate speech to text conversion or real time translation for people from different languages. For example, a person with hearing difficulties could use Chatgpt to write, or take questions. The feature of such services makes it possible for any person with or without disability to access information and or services as deemed suitable. Additionally, it is easy for Chatgpt to be incorporated to suit multiple languages this will help businesses to take their services worldwide to ensure that they give the customers in foreign countries an experience of business in their local regions [42]. This may be rather useful for companies with operations worldwide who sometimes have to translate not only the concepts, but also the attitude to these concepts in a particular language and with respect to some localisms.

It has attempted to look at the feasibility and possibilities of Chatgpt in various fields, but it is important to note the ethical aspect, and concerns with its use. For example, in achieving impressively genuine conversation, issues such as misinformation, privacy, and data security come to play. Of the Chatgpt systems, the design needs to be controlled very well so as not to build a system that will produce wrong or destructive information. In addition, because AI consumes extensive amounts of information, enterprises must state how user data are processed to meet the legal guidelines of private-life protection laws like GDPR. The last issue is the problem of the origin of the data which was used to train conversational AI agents. Since the Chatgpt was trained from Human generated data it acts almost like a parrot mimicking its teacher along the line of the bias society or even producing an indecent content. Addressing all these concerns requires ongoing efforts to improve the training paradigms and advocating for mid applications of AI [43].

Here, it is underlying a new round of conversational AI models as a generation of new business applications by redefining its customer and client interface and also its internal environment for learning. Making customer service more effective, enhancing sales and marketing techniques, reducing time for inter and intercompany/interdepartmental communications, making it more accessible, Chatgpt is setting the stage for the future in which AI-driven conversations will become

the future of global business [44]. As a result of new innovations in technology and solution to the issues of ethicality, Chatgpt will transform the mode of communication in various fields to improve efficiency in customer relation and satisfaction.

Conclusion

Artificial Intelligence is becoming one of the most successful systems that helps fast-growing economic development and driving change in business around the globe; in healthcare, petroleum, fraud detection, cybersecurity and conversational AI. From helping doctors do diagnosis and decide on the correct treatment all the way through the patient, it has been shown in the petroleum industry to be an intelligent system capable of solving challenges and even risk assessment and optimization as well as productivity. In fraud detection as one of the applications of Artificial Intelligence, it enhances techniques of identification and prevention of fraudulent activities so as to reduce the likely hood on fraud and undesirable reputation. Similarly in security, innovation thru ACT solutions is strengthening security against new threats in the world increasing cyber threats and cyber security the risks and coming with immediate security protection and security prediction and even dealing with security solutions to any cyber threat to the data. The examined case of Chatgpt, as one of the main reps of conversational AI, also stresses the role of AI to shift the model of business-customer relations. Since such sophisticated interfaces such as Chatgpt respond not only asynchronously, but also provide refining cu ration of outbound messages, customer support has been improved; sales approaches have declared; and, new possibilities of communication have been opened. Besides, these enhancements have been also implemented to the internal business applications as well on the client side applications that effectively maintain the total organizational functionality.

Nevertheless, as AI becomes an increasingly ubiquitous part of not just technological infrastructure but also organizational management and personal environments, there are pressing questions of ethics: what is the proper way to work with data in contexts that involve artificial intelligence, and how might AI perpetuate unjustifiable bias rather than neutrality? Challenging industry leaders to look at how the still-evolving AI tech must unquestionably and powerfully work reach and actuate

the promised positive change toward sustaining the bedrock of trust and accountability will be the key test. In the future, higher interest in Artificial Intelligence is considered to continue to build more pressure, and broaden the spheres of application in various fields. Given that AI is still an emerging science that is still growing and evolving many facets of the business and, indeed, of people's lives will be impacted and influenced as the underlying technologies improve and evolve; specifically
